What are the different validity conditions we've learned, and how do I know which one to use in a given problem?

What are the different types of null distributions we've encountered? What are their hypothesized means and standard deviations?

What is a confidence interval? Why are they important/useful? What are the different ways we can construct them?

What is the 3S Strategy, and why is it useful?

What is random sampling? What is random assignment? How do they relate, and what are their implications?

How can I tell what the null and alternative hypotheses are?

What are the two things we should always do with a *p*-value? How do these two things differ?
